Executive Summary

In June of 1988, the Parliament of Canada proclaimed the Canadian Environmental Protection Act (CEPA).

A great deal of knowledge about toxic chemicals is needed to successfully implement CEPA. Their use, toxicity, fate in the environment and effects on wildlife are examples of what needs to be known to assess the full impact of toxic chemicals on the biosphere.

In order to focus the efforts of government agencies involved in implementing CEPA, a Priority Substances List (PSL) has been created. On it can be found the name of substances that are suspected of having adverse environmental effects and should thus be of immediate concern.

In response to the need for knowledge about toxic substances mentioned on the PSL, the Water Quality Branch/Atlantic Region has undertaken a comprehensive compilation of its own data banks and the preparation of summary reports.

Arsenic is a toxic substance appearing in Group 1 of the PSL. This report summarizes the information the Water Quality Branch/Atlantic Region has on its concentrations in Atlantic Canada's environment.

Abstract

This report was initiated in support of the new Canadian Environmental Protection Act (CEPA). It summarizes over 20 years of arsenic data generated by the Water Quality Branch in the Atlantic Region.

Arsenic analysis was performed on more than 3700 samples encompassing streams, lakes, estuaries, ground water wells, mining wastes, precipitation, sediments and fish.

For the most part, arsenic concentrations in Atlantic Canada's environment seem to be due to natural processes. Arsenic concentrations in stream, lake and estuary waters were found to be below the guideline value of 0.05 mg/L, with more than half the samples below detection limit. Except for five samples analyzed in 1971, all ground water and spring water samples were found to have arsenic concentrations below the guideline value of 0.05 mg/L.

The results for precipitation samples were found to be inconclusive and the study should be repeated. Arsenic concentrations in fish and sediment samples were found to be within a range that is considered normal; 0.001 to 0.266 mg/kg in most fish samples, and 0.08 to 260 mg/kg in sediment samples. As expected, some sediments collected near mining sites exhibited higher arsenic concentrations, confirming that mining activities can be anthropogenic sources of arsenic in the environment.

Results generated prior to 1981 for water samples seemed to be biased high compared to post-1980 results. Unfortunately, the lack of valid quality control samples in the database precluded determining which results represented "true" arsenic concentrations in the environment. It was nonetheless concluded that arsenic is not at the moment a problem compound in Atlantic Canada's environment.

Sommaire

Ce document a été rédigé à l'intention de la Loi Canadienne pour la Protection de l'Environnement (LCPE). Il résume des données sur l'arsenic recueillies depuis plus de 20 années par la Direction de la Qualité des Eaux pour la région de l'Atlantique.

Environ 3700 échantillons ont été analysés provenant de cours d'eau, de lacs, d'estuaires, d'eaux souterraines, de rejets de mines, de sédiments et de poissons.

En général, les concentrations d'arsenic dans l'environnement des provinces de l'Atlantique semblent être le résultat de processus naturels. Les concentrations d'arsenic dans les cours d'eau, les lacs et les estuaires étaient inférieures à l'objectif de 0,05 mg/L, et plus de la moitié se trouvaient au-dessous du seuil de détection. À l'exception de 5 échantillons analysés en 1971, tous les échantillons d'eau souterraine et d'eau de source ont démontré des concentrations d'arsenic inférieures à 0,05 mg/L. Il a été déterminé que les résultats d'analyse des échantillons de précipitation étaient inconcluants et que l'étude devrait être répétée. Les concentrations d'arsenic dans les poissons et les sédiments étaient à l'intérieur de normes acceptables; de 0.001 à 0.266 mg/kg dans la plupart des échantillons de poissons, et de 0.08 à 260 mg/kg dans les sédiments. Comme prévu, des sédiments prélevés à proximité de sites miniers ont démontré des concentrations plus élevées d'arsenic, confirmant ainsi que les activités minières peuvent être une source anthropogénique d'arsenic dans l'environnement.

Les résultats générés avant 1981 semblaient donner des valeurs plus élevées comparés à ceux obtenus après 1980. Malheureusement, le manque d'échantillons valides de contrôle de qualité dans la base de données a empêché de déterminer quels résultats représentaient les "vraies" concentrations d'arsenic dans l'environnement. Il a été tout de même conclu que l'arsenic n'est pas à l'heure actuelle un composé problème dans les provinces de l'Atlantique.

1. Introduction

In June of 1988, the Parliament of Canada proclaimed a new law, the Canadian Environmental Protection Act (CEPA). Its purpose is to better protect Canadians from pollution by reinforcing the government's abilities to monitor and control toxic chemicals throughout their life cycle. This has often been referred to as the "cradle to grave" approach, meaning that toxic chemicals must be controlled from their very beginning, at the development stage, throughout their manufacturing, storage, transportation, use, disposal and fate in the environment.

A great deal of knowledge about toxic chemicals is thus needed to successfully implement CEPA. Their use, toxicity, fate in the environment and effects on wildlife are examples of what needs to be known to assess the full impact of toxic chemicals on the biosphere.

In order to focus the efforts of government agencies involved in implementing CEPA, a Priority Substances List (PSL) has been created. On it can be found the name of substances that are suspected of having adverse environmental effects and should thus be of immediate concern.

In response to the need for knowledge about toxic substances mentioned on the PSL, the Water Quality Branch/Atlantic Region has undertaken a comprehensive compilation of its own data banks and the preparation of summary reports.

Arsenic is a toxic substance appearing in Group 1 of the PSL. This report summarizes the information the Water Quality Branch/Atlantic Region has on its concentrations in Atlantic Canada's environment.

1.1 Arsenic

Arsenic is an element naturally present in the environment, where it is found under various chemical forms, mostly in mineral deposits. It can be found in significant quantities in sedimentary rocks, shales, argillites, igneous rocks and coal. It is used industrially in the production of glass, metals, pigments and semi-conductors, and some arsenic compounds have also been used as pesticides (NRCC, 1978).

In Canada, in 1978, six arsenic compounds were still registered for use as herbicides, wood preservatives, in paints and adhesives, and as pesticides to control ants, earthworms and apple maggots (NRCC, 1978).

Arsenic finds its way into lakes, rivers and other parts of the environment through natural erosion of soils and rocks. But the industrial smelting of gold, copper, zinc and lead ores, the combustion of fossil fuels and the agricultural use of arsenical pesticides have been important sources of arsenic contamination (Environment Canada, 1979).

In Canada, problems with arsenic have arisen from the processing of gold and uranium ores as well as from wells sunk into arseniferous rocks. Nova Scotia is the site of substantial mineral deposits containing arsenic and this has caused problems with some domestic wells (NRCC, 1978 and Environment Canada, 1986).

General background concentrations of arsenic in water usually average less than 0.01 mg/L; in sea water, less than 0.003 mg/L; and in soil, less than 15 mg/kg, although soil concentrations near mineral deposits can be as high as 400-900 mg/kg (NRCC, 1978).

In sufficiently high amount, arsenic can be toxic to many life forms including humans. It is toxic to beans, peas and rice plants at concentrations of 10 to 25 mg/kg in soil. Some fish species show signs of toxicity after 2-3 days exposure to 1 to 2 mg/L in water. In humans, daily intakes of 0.15 to 0.60 mg of arsenic can produce symptoms of chronic poisoning, and excessive exposure has been associated with respiratory cancer, nervous system disorders and dermatitis (NRCC, 1978).

The Canadian guidelines for arsenic in various water types can be found in table 1.

2. Results and Discussion

2.1 Arsenic Data

Between 1966 and 1989, 3766 arsenic samples were collected and analyzed by the WQB-AR. The samples were collected from numerous locations throughout the Atlantic Provinces. Table 2 shows the distribution of arsenic samples by provinces and sample types.

In New Brunswick, most of the samples (69%) originated from streams and were collected mainly during the 1970's. The Saint John river and its tributaries were the focus of much attention along with the Saint Croix river, dividing the US and New Brunswick. Other sites surveyed in N.B. were the Restigouche river and the Kedgwick and Upsalquitch rivers flowing into it; in the Bathurst area, the attention focused on mining areas and on rivers flowing into Chaleur Bay; the Miramichi river, flowing from North of Fredericton to Chatham has been surveyed along with many streams flowing into it; and in South-Eastern N.B., a few dozen samples have been analyzed, covering the Kouchibouguac, Coal Branch, Buctouche, Cocagne, Richibucto, and Peticodiac rivers. A few fish and sediment samples have also been analyzed as part of a special study on heavy metals in biota. Also, mining effluents from selected settling ponds and tailing ponds have been analyzed for arsenic. Finally, between 1985 and 1989, the water supply sources of 37 municipalities were tested for arsenic as part of an extensive survey of toxic chemicals in municipal drinking water sources (Environment Canada, 1990).

Table 1: Canadian guidelines for arsenic in water (CCREM, 1987).

Water Type	Guideline
drinking water	0.05 mg/L
drinking water sources	0.05 mg/L
water for aquatic life	0.05 mg/L
water for irrigation	0.10 mg/L

Table 2: Distribution of valid arsenic samples by provinces and type of samples.

TOTAL	1762	1030	307	667	3766

In Nova Scotia, 58% of the samples came from various streams and 17% from lakes. Among the sites surveyed were the Annapolis, Avon and Shubenacadie rivers, Falls Lake, lakes Thomas, Third and Fletcher, and the rivers Salmon, Philips, East, Mersey, Medway, La Have, Sackville, Margaree, Grand and Mira. Also, 92 sediment samples and 44 fish samples, mostly from the Salmon and Mira rivers, were analyzed for arsenic. The water supply sources of 38 municipalities were also tested for arsenic.

In Newfoundland and Labrador, 68% of the samples came from streams and 27% from lakes. Among the sites surveyed were the Churchill and Eagle rivers in Labrador, the St. Genevieve, Torrent and Harrys rivers, the Indian brook and Exploits river (near mining activities), the Gander, Terra Nova and Isle aux Morts rivers, and the Salmon, Garnish, Pipers Hole and Come by Chance rivers. Also, 19 sediments, mostly from Red Indian Lake, were analyzed for arsenic and so were the water supply sources of 40 municipalities.

On Prince Edward Island, 52% of the samples came from ground water, 27% from streams and only 5% from lakes. Most of the sampling was done in 1977-79, as part of the Federal-Provincial agreements, and between 1986-1989 as part of the survey of municipal drinking water sources. Among the rivers surveyed were the Mill, Dunk, North, West and Morell rivers. Most of the ground water samples came from the municipalities of Charlottetown, Georgetown, Kensington, Parkdale, Souris, St. Eleanors, Summerside and North Rustico. Also, 10 sediment samples and 20 fish samples were analyzed for arsenic.

The results of all arsenic analysis can be found in appendices B and C.

In order to facilitate the viewing of such an amount of information, the data has been graphically represented in figures 3 to 18.

Figure 1 shows the location of sub-basins, while figure 2 shows a description of the graphs. Note that the Y scale, representing concentration, is a log scale and that the size of each point in the graph represents the number of samples that showed a given concentration. "Less than" (L) values were plotted as 100 times less the specified value and appear in the lower portion of the graphs, usually below the detection limit lines. Values reported as 0.00 or L 0.00 were plotted at the bottom of the graphs.

2.1.1 Streams

Arsenic concentrations in streams are represented in figures 3 to 6. Except for four values in New Brunswick (see fig. 3), all the samples showed arsenic concentrations below the guideline value of 0.05 mg/L. The four stream samples showing arsenic concentrations above 0.05 mg/L were from Black Brook (0.054 mg/L), Waterloo lake outlet (0.084 mg/L) and Nigadoo river (0.340 mg/L and 0.190 mg/L). In all cases, samples taken at the same sites during subsequent months or years showed arsenic concentrations below the guideline value (0.05 mg/L) and often below the detection limit (0.005 mg/L). This suggests that these elevated values were either

isolated occurrences or erroneous values and that all the streams surveyed do meet the guideline. It is significant to note that these four elevated values were generated between 1970 and 1972, at a time when less emphasis was put on quality control.

2.1.2 Lakes and Estuaries

Arsenic concentrations in lakes and estuaries are represented in figures 7 to 11. All lake and estuary samples showed arsenic concentrations below the guideline value of 0.05 mg/L.

2.1.3 Ground Water

Arsenic concentrations in ground water (spring water included) are represented in figure 12. All samples showed arsenic concentrations below the guideline value of 0.05 mg/L with the exception of five samples analyzed in 1971. Of these, four were from a private well in Fredericton, with concentrations ranging from 0.130 to 0.269 mg/L. One sample was from a spring (0.460 mg/L), also in Fredericton. Unfortunately, no subsequent sampling was done and it is not known if these values are accurate. It is interesting to note that only six ground water samples were analyzed in 1971, of which five are the anomalous ones. All other values were generated between 1986 and 1989 and are all below the guideline value (0.05 mg/L).

2.1.4 Mining Wastes

Mining waste samples were collected mostly from settling ponds used by the mining industry. Detectable concentrations of arsenic in such samples varied from 0.005 mg/L to 1.9 mg/L (fig. 13). There are no guidelines for arsenic in mining wastes, but as expected, many samples were above 0.05 mg/L.

2.1.5 Precipitation

Eighty-two rain samples were analyzed for arsenic in 1981 as part of a joint study with the Université de Moncton. The results are represented in figure 14. As can be seen, the data encompassed a wide range of concentrations; from less than detection limit (0.001 mg/L) up to 0.950 mg/L (a factor of nearly 1000). Such a wide range and high values are surprising for precipitation samples, especially when they exceed those found for ground water samples (fig. 12). This study should clearly be repeated. In the meantime, these results for precipitation should be used with caution.

2.1.6 Sediments

Arsenic concentrations in various type of sediments can be found in figures 15 to 17. Concentrations varied from 0.08 mg/kg up to 260 mg/kg, with most samples in the "normal" range of 1 to 10 mg/kg. Sediments vary greatly in composition and it is thus not surprising that they exhibited a wide range of arsenic concentrations. As expected, the samples showing the highest concentrations were those near mining areas (sub-basins BQ and YN). There are no guidelines for arsenic in sediments.

2.1.7 Biota

Arsenic concentrations in fish samples are represented in figure 18. The concentrations in fish ranged from L 0.001 up to 2.677 mg/kg, but most samples were within the range of 0.001 to 0.266 mg/kg. Similar values have been found in other studies on fish and are considered normal (NRCC, 1978).

2.2 Trends

Whenever a large set of data is examined, as in this study, the question of temporal trends inevitably arises. But assessing trends requires a large set of consistent data. Unfortunately, in this case, few sites have been surveyed long enough and often enough to provide reliable trend analysis. Nonetheless, in an effort to spot global trends that might have developed over the years, a boxplot was produced (fig. 19) that shows detectable arsenic concentrations in stream and lake waters over the years.

Immediately noticeable is the sharp decline in arsenic values between 1980 and 1981; a distinctive 10 fold drop in measurable arsenic concentrations. Close examination of the data even allowed one to pinpoint the drop to late 1980. This decline was found to correspond exactly to a period when the analytical method was changed from colorimetry to atomic absorption (with a corresponding ten fold drop in detection limit).

Some serious implications emanate from these findings. If a change of method and a drop of 10x in the detection limit caused a drop of 10x in the detected values, what are the real arsenic concentrations? Are all pre-1981 arsenic levels an overestimation of "true" values?

The lack of valid quality control data - most arsenic QC samples in the database have invalid station numbers - makes it difficult to answer these questions. But it is significant to note that 47% of the pre-1981 arsenic values were below the detection limit values, i.e. not detectable or "less than" values. Of the 53% remaining detected concentrations, about 78% were within 3 times the detection limit, a range where the possibility of false positives is more predominant.

With a new method presenting a detection limit 10 times lower, and hence a better ability to detect lower amounts of substances, one would expect to see a higher percentage of positive values in samples analyzed by such a method. But in this case, it didn't happen. The post-1980 data actually showed a higher percentage (71%) of "less than" values. Of the 29% remaining detected values, a high 67% were within 3 times the detection limits.

It is thus the author's opinion that pre-1981 results are in general an overestimation of "true" arsenic concentrations in our lakes and streams. In fact, true arsenic concentrations may even be lower than what was found post-1980 by the atomic absorption method, if one takes into account the high number of "less than" values and also the high number of values within three times the detection limits. In all probability, concentrations of arsenic in most streams and lakes in Atlantic Canada that are not subjected to direct input of arsenic (like settling ponds) are probably well below the guideline value of 0.05 mg/L.

2.3 Quality Control

The lack of quality control samples in the database to support the arsenic data has already been pointed out. In fact, no blanks or spikes have ever been routinely submitted to the laboratory for arsenic analysis. Consequently, very few QC samples were found in the database. Only 4 blank and 10 interlaboratory QC samples could be validated as formal QC samples.

The four blank samples (500826 - 500829) consisted of Millipore™ water. They were analyzed in 1985 for project 211 (toxic chemicals survey) and showed no detectable arsenic (i.e. less than 0.0002 mg/L).

The 10 interlaboratory QC samples (003651, 003652, 100748, 100751, 101481, 101484, 200932, 401918-401920) consisted of water, fish and sediment samples analyzed between 1980 and 1984 as part of various QC studies. Unfortunately, the final results of those studies could not be found either in-house or procured from the library in Ottawa or from the original authors. It seems that the findings of those particular studies were never published as IWD reports.

The only samples left that qualified as QC were in the form of duplicate and triplicate water samples. Such samples were routinely collected and analyzed since nearly the beginning of arsenic analysis by the WQB-AR laboratory. Most of the times, these replicates were analyzed together, not weeks or months apart, and thus only gave a measure of the "on the spot" repeatability of the analytical protocol used at the time.

To get a measure of this repeatability, the arsenic replicates, mostly duplicates, were correlated one against the other. The correlation coefficient, R, was taken as an indication of repeatability. Because of the difference in pre-1981 and post-1980 data, two measurements were made, one for each period.

A correlation coefficient of 0.996 was found for the 116 post-1980 water replicates, indicating excellent agreement between them. A somewhat lower correlation coefficient of 0.893 was found for the 204 pre-1981 replicates, nevertheless indicating good agreement between them. The repeatability of water replicates was thus considered acceptable regardless of the analytical method used.

The same calculations were applied to 13 triplicate sediment samples found in the database. A correlation coefficient of 0.943 was obtained for these samples, indicating very good repeatability for sediment samples.

Not enough fish sample replicates could be identified to provide a meaningful evaluation of repeatability.

Unfortunately, the questions of accuracy, precision and long term repeatability of arsenic analysis will remain mostly unanswered until the QC protocol is expanded to include blank and, more importantly, spike samples.

3. Conclusion

This report was initiated in support of the new Canadian Environmental Protection Act (CEPA). It summarized over 20 years of arsenic data generated by the Water Quality Branch in the Atlantic Region.

Arsenic analysis was performed on more than 3700 samples encompassing streams, lakes, estuaries, ground water wells, mining wastes, precipitation, sediments and fish.

For the most part, arsenic concentrations in Atlantic Canada's environment seem to be due to natural processes. Arsenic concentrations in stream, lake and estuary waters were found to be below the guideline value of 0.05 mg/L, with more than half the samples below detection limit. Except for five samples analyzed in 1971, all ground water and springwater samples were found to have arsenic concentrations below the guideline value of 0.05 mg/L. None of the five anomalous samples were ever re-analyzed so that the results could not be confirmed. In all likelihood, those samples came from a contaminated private well and represent an isolated occurrence of high arsenic concentrations in water. The results for precipitation samples were found to be inconclusive and the study should be repeated. Arsenic concentrations in fish and sediment samples were found to be within a range that is considered normal. As expected, some sediments collected near mining sites exhibited higher arsenic concentrations, confirming that mining activities can be anthropogenic sources of arsenic in the environment.

Results generated prior to 1981 for water samples seemed to be biased high compared to post-1980 results. Unfortunately, the lack of valid blank and spike samples precluded determining which results represented "true" arsenic concentrations in the environment. If the post-1980 results represent "true" arsenic concentrations, then it is concluded that arsenic is not at the moment a problem compound in Atlantic Canada's environment.

APPENDIX A

The Water Quality Branch - Atlantic Region database

Searching the WQB-AR Database

At the time of this writing, the WQB-AR database was divided into three sections: pre-1980 data, 1980-1989 data and post-1989 data. The data was retrieved with the program RS1PERM by specifying a date range and the method codes for arsenic (also known as parameter codes). The method codes used for each section of the database are listed in table 3.

The pre-1980 section was searched using the date range 01/01/63 to 31/12/80, while the post-1980 sections were searched using the date range 01/01/79 to 31/12/89.

The upper range of the search was limited to 1989 data because that portion of the database is fairly static now; very little change should occur in that section of the database. In contrast, 1990 data is at the moment (February 1991) still being produced and entered in the database. The data presented in this report is current as of January 1991.

The Arsenic Data

Table 4 shows the number of values per parameter code resulting from the pre-1980 database search. As can be seen, 2221 values were found for 2204 samples (17 samples were analyzed by two methods). All samples were valid i.e. none were quality control samples, spiked samples, reference material samples or special project (invalid station number) samples.

Table 5 shows the number of values per parameter code resulting from the post-1980 database search. As can be seen, 1765 values were found for 1758 samples (seven samples were analyzed by two methods). Not all samples were valid; 192 samples showed invalid station numbers (e.g. 00NB00000000) and four samples were listed as blanks. Table 6 shows the number of values per parameter code with invalid samples excluded.

A verification of samples showing invalid station numbers proved them to be interlab QC study samples, unidentified test samples, one-time grab samples outside existing sampling stations or special project samples. The great majority of them were real samples that for some reasons were not assigned proper station numbers.

A certain number of manipulations were necessary to bring the data into a format suitable for plotting and publishing. First, invalid samples were removed and placed in a separate table (see appendix C). Then, samples showing two values were transformed so that one value only was left in the table. Those values were usually the result of a comparison between a new or experimental method and the one used routinely. In all cases, the value coming from the routine method was chosen, but very often both values were similar. Finally, all values were reported to one column labelled "arsenic" and both tables (pre-1980 and post-1980) were combined into one working table of 3766 samples. This table of "valid" arsenic samples, which was sorted by sample type and by value, can be found in appendix B.

For information purposes, the number of valid arsenic samples per sub-ID (or project number) is presented in table 7.

Table 3: NAQUADAT method codes for arsenic and their description.

method code ¹ pre-1980 post-1980		unit	description
33001L		mg/L	arsenic total, APDC
33003L 33003P		mg/L	arsenic total, colorimetry with silver diethyldithiocarbamate (SDDC)
33006L 33006L		mg/L	arsenic total, colorimetry with SDDC
33007L 33007L 33007P		mg/L	arsenic total, flameless atomic absorption (AA)
33054L		mg/kg	arsenic non-residual, sediment, flameless AA
33101L		mg/L	arsenic dissolved, colorimetry with SDDC
33103L 33103L 33103P 33103P		mg/L	arsenic dissolved, colorimetry with SDDC
33104L		mg/L	arsenic dissolved, flameless AA
33303L 33303P		mg/L	arsenic extractable, colorimetry with SDDC
33601L		mg/kg	arsenic, fish tissue, flameless AA

¹ the letter following each method code is the "place of analysis" code,
L = laboratory, P = preserved.

APPENDIX B

Valid arsenic data sorted by sample type and by value

Explanation of Table

STN = station number: a 12-digit code containing information about the sample.

Digits 1 and 2 represent the sample type (see table 2).

Digits 3 and 4, the province code.

Digits 5 and 6, the basin code.

Digits 7 and 8, the sub-basin code (see figure 1)

Digits 9 to 12 are a numerical code assigned by the regional office.

SAMPLE = sample number assigned by the laboratory

SDATE = sampling date

SUBID = number representing the project for which the sample was collected (see table 7)

ARSENIC = reported concentration of arsenic found in sample, either in mg/L or mg/kg depending on the sample type

0	1 STN	2 SAMPLE	3 SDATE	4 SUBID	5 ARSENIC	0	1 STN	2 SAMPLE	3 SDATE	4 SUBID	5 ARSENIC
